

# Recap of OO concepts

Objects, classes, methods and more.

# Classes and Objects

---

- A class defines a group of related methods (functions) and fields (variables).
- An object is a single instance of a class i.e. an object is created from a class.
- Objects can be related to real-world artefacts.
- Many objects can be constructed from a single class definition.
- Each object must have a unique name within the program.

# Spot Class

<i>Spot</i>
<i>xCoord</i> <i>yCoord</i> <i>diameter</i>
<i>Spot()</i> <i>Spot(float, float, float)</i> <i>display()</i> <i>getXCoord()</i> <i>getYCoord()</i> <i>getDiameter()</i> <i>setXCoord(float)</i> <i>setYCoord(float)</i> <i>setDiameter(float)</i> <i>toString()</i>

Two objects. Each has a unique name and it's own copy (values) of the fields.

# Object State

There are two objects of type Spot.

Each object has a unique name:

innerSpot

outerSpot

Each object has a different

**object state:**

each object has it's own copy of the fields (xCoord, yCoord, diameter) in memory and has it's own data stored in these fields.

# Spot Class

---

Define the class as public

```
public class Spot
```

```
{
```

```
    private float xCoord, yCoord;  
    private float diameter;
```

```
}
```

Declare the  
fields in the  
class as  
private

# Constructor(s)

```
public class Spot
{
    private float xCoord, yCoord;
    private float diameter;
```

//Default Constructor

```
public Spot()
{
}
```

//Constructor to initialise all instance fields.

```
public Spot(float xCoord, float yCoord, float diameter)
{
    this.xCoord = xCoord;
    this.yCoord = yCoord;
    this.diameter = diameter;
}
```

- **Spot()** is the default constructor that is called to build an object in memory.
- A constructor is a method that has the same name as the class but has no return type.

# Getters

Accessor methods return information about the state of an object.

A **'getter'** method is a specific type of accessor method and typically:

- contains a return statement (as the last executable statement in the method).

- defines a return type.

- does NOT change the object state.

```
public class Spot
{
    private float xCoord, yCoord;
    private float diameter;

    //constructors...

    // getters //
    public float getDiameter(){
        return diameter;
    }

    public float getXCoord(){
        return xCoord;
    }

    public float getYCoord(){
        return yCoord;
    }
}
```

# Getters

---

visibility modifier      return type      method name      parameter list (empty)

```
public float getDiameter()  
{  
    return diameter;  
}
```

return statement

start and end of method body (block)

The diagram illustrates the components of a Java getter method. The code snippet is: `public float getDiameter()  
{  
 return diameter;  
}`. Annotations with arrows point to specific parts: 'visibility modifier' points to 'public', 'return type' points to 'float', 'method name' points to 'getDiameter()', and 'parameter list (empty)' points to '()'. The method body is enclosed in curly braces, with an arrow pointing to the opening brace labeled 'start and end of method body (block)'. The statement 'return diameter;' is labeled 'return statement'.

# Setters

Mutator methods change (i.e. mutate!) an object's state.

A **'setter'** method is a specific type of mutator method and typically:  
contains an assignment statement  
takes in a parameter  
changes the object state.

```
public class Spot
{
    private float xCoord, yCoord;
    private float diameter;

    //constructors...
    // getters...
    //   setters   //
    public void setDiameter(float diameter){
        this.diameter = diameter;
    }

    public void setXCoord(float xCoord){
        this.xCoord = xCoord;
    }

    public void setYCoord(float yCoord){
        this.yCoord = yCoord;
    }
}
```

# Setters

---

The diagram illustrates the components of a Java setter method. The code is: `public void setDiameter(float diameter) { this.diameter = diameter; }`. Annotations with arrows point to specific parts: 'visibility modifier' points to 'public'; 'return type' points to 'void'; 'method name' points to 'setDiameter'; 'parameter' points to 'float diameter'; 'field being mutated.' points to 'this.diameter'; 'assignment statement' points to '='; and 'Value passed as a parameter' points to 'diameter'.

visibility modifier

return type

method name

parameter

```
public void setDiameter(float diameter)
{
    this.diameter = diameter;
}
```

field being mutated.

assignment statement

Value passed as a parameter

# Getters/Setters

---

- For **each instance field** in a class, you are normally asked to write:
  - A getter
  - A setter

# Improving the constructor with validation

```
public Spot(float xCoord, float yCoord, float diameter)
{
    this.xCoord = xCoord;
    this.yCoord = yCoord;
    this.diameter = diameter;
}
```

```
public Spot(float xCoord, float yCoord, float diameter)
{
    this.xCoord = xCoord;
    this.yCoord = yCoord;
    if ((diameter > 0) && (diameter < 500)) {
        this.diameter = diameter;
    }
    else{
        this.diameter = 10;
    }
}
```

**Note:** in the constructor, you typically set the field to a default value if invalid data was entered.

# Improving the setter

---

```
public void setDiameter(float diameter) {  
    if ((diameter > 0) && (diameter < 500)) {  
        this.diameter = diameter;  
    }  
}
```

Note: The validation done at constructor level must be repeated at setter level for that field → data integrity!

However, in setter methods, you typically do not update the field's value if invalid data was entered (notice how the “else” part of the “if” is not there).

# toString()

---

```
public class Spot
{
    private float xCoord, yCoord;
    private float diameter;

    //constructors...
    //getters...
    //setters...

    public String toString()
    {
        return "(" + xCoord + "," + yCoord + "). Diameter is: " + diameter;
    }
}
```

# toString()

---

- The toString() method returns a string version of an object.
- This is a useful method and you will write a toString() method for most of your classes.
- When you print an object, Java automatically calls the toString() method e.g.

```
Spot spot = new Spot();
```

```
//both of these lines of code do the same thing
```

```
System.out.println(spot);
```

```
System.out.println(spot.toString());
```

# Other Methods

<i>Spot</i>
<i>xCoord</i> <i>yCoord</i> <i>diameter</i>
<i>Spot()</i> <i>Spot(float, float, float)</i> <b><i>display()</i></b> <i>getXCoord()</i> <i>getYCoord()</i> <i>getDiameter()</i> <i>setXCoord(float)</i> <i>setYCoord(float)</i> <i>setDiameter(float)</i> <i>toString()</i>

```
public class Spot
{
    private float xCoord, yCoord;
    private float diameter;

    //constructors...
    //getters...
    //setters...

    public void display()
    {
        ellipse(xCoord, yCoord, diameter, diameter);
    }
}
```

# Using the Spot Class

---

Declaring an object **sp**, of type **Spot**.

`Spot sp;`

Calling the **Spot(float, float, float)** *constructor* to build the **sp** object in memory.

`sp = new Spot(40,30,45);`

Calling the display method, over the **sp** object.

`sp.display();`

# Questions?

---
